4	Draft chapter for The International Pharmacopoeia
5	(December 2018)
6	DRAFT FOR COMMENTS
7	
9 10 11 12 13 14 15 16	Please send any comments you may have on this draft to Dr Herbert Schmidt , Medicines Quality Assurance Programme, Technologies Standards and Norms, Department of Essential Medicines and Health Products, World Health Organization, 1211 Geneva 27, Switzerland; email: <u>schmidth@who.int</u> , with a copy to Ms Sinéad Jones (email: jonessi@who.int) by 28 February 2019 . In order to speed up the process for receiving draft monographs and for sending comments, please send us your email address and we will add it to our electronic mailing list. Please specify if you wish to receive monographs.
$\begin{array}{c} 17\\ 18\\ 20\\ 22\\ 22\\ 22\\ 22\\ 22\\ 22\\ 22\\ 22\\ 22$	All rights reserved. This draft is intended for a restricted audience only, i.e. the individuals and organizations having received this draft. The draft may not be reviewed, abstracted, quoted, reproduced, transmitted, distributed, translated or adapted, in part or in whole, in any form or by any means outside these individuals and organizations (including the organizations' concerned staff and member organizations) without the permission of the World Health Organization. The draft should not be displayed on any website. Please send any request for permission to: Dr Sabine Kopp, Manager, Medicines Quality Assurance Programme, Technologies Standards and Norms, Department of Essential Medicines and Health Products, World Health Organization, CH-1211 Geneva 27, Switzerland, fax: +41 22 791 4856; email: kopps who.int. The designations employed and the presentation of the material in this draft do not imply the expression of any opinion whatsoever on the part of the World Health Organization concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted lines on maps represent approximate border lines for which there may not yet be full agreement. The mention of specific companies or of certain manufacturers' products does not imply that they are endorsed or recommended by the World Health Organization in preference to others of a similar nature that are not mentioned. Errors and omissions excepted, the names of proprietary products are distinguished by initial capital letters. All reasonable precautions have been taken by the World Health Organization to verify the information contained in this draft. However, the printed material is being distributed without warranty of any kind, either expressed or implied. The responsibility for the interpretation and use of the material lies with the reader. In no event shall the World Health Organization be liable for damages arising from its use.

 SCHEDULE FOR THE ADOPTION PROCESS OF DOCUMENT QAS/17.716:

DRAFT CHAPTER FOR *THE INTERNATIONAL PHARMACOPOEIA* POLYMORPHISM

Drafting of the text by a WHO Expert.	March 2017
Discussion at the informal consultation on quality control laboratory tools and specifications for medicines.	2–4 May 2017
Draft text sent out for public consultation.	July–September 2017
Presentation to the Fifty-second WHO Expert Committee on Specifications for Pharmaceutical Preparations.	October 2017
First revision drafted based on the comments received during the public consultation.	March 2018
Discussion at the consultation on screening technology, sampling and specifications for medicines.	2–4 May 2018
Revision 1 sent out for public consultation.	June – July 2018
Second revision drafted based on the comments received during the public consultation.	October 2018
Presentation to the Fifty-third WHO Expert Committee on Specifications for Pharmaceutical Preparations.	October 2018
Revision 2 sent out for public consultation.	December 2018 – February 2019
Further follow-up action as required.	

59	[Note from the Secretariat. It is proposed to publish the following chapter on Polymorphism			
60	in the Supplementary Information section under "Notes for guidance".			
61				
62	The text was revised based on the comments received during the last public consultation in			
63	June – July 2018 (see history).]			
64				
65	POLYMORPHISM			
66				
67	1. INTRODUCTION AND TERMINOLOGY			
68				
69	The aim of this chapter is to provide a brief overview of:			
70				
71	• the terminology associated with crystal polymorphism;			
72	• some analytical techniques commonly used to characterise polymorphs;			
73	• the relevance of polymorphism for active pharmaceutical ingredients (APIs) and			
74	finished pharmaceutical products (FPPs); and			
75	• the control strategies for polymorphism employed by The International			
76	Pharmacopoeia.			
77				
78	APIs and excipients, in the solid phase, can be classified as either crystalline or non-			
79	crystalline solids. A crystalline structure implies that the structural units (i.e. the unit cells)			
80	are repeated in a long range order (i.e. three dimensional crystal lattice). The arrangement of			
81	atoms and/or molecules in an amorphous solid is non-ordered (i.e. does not have a long range			
82	order), or random system, analogous to the liquid state, and does not possess a			
83	distinguishable crystal lattice. Amorphous solids are classified as non-crystalline solids.			
84				
85	Variation in the crystallization conditions (temperature, pressure, solvent composition,			
86	concentration, rate of crystallization, seeding of the crystallization medium, presence and			
87	concentration of impurities, etc.) may cause the formation of different crystalline forms.			
88				
89	When a chemical element (e.g. sulfur) exists in different crystalline forms, it is referred to as			
90	allotropy, not polymorphism (1). When a chemical compound with a given chemical			
91	structure crystallizes in more than one crystalline lattice with different unit cells, these			

92 crystalline phases are called *polymorphs* and the phenomena is referred to as *polymorphism*.
93 The difference in internal crystal structure could be attributed to differences in molecule
94 packing arrangements and/or different molecular conformations. Polymorphic substances,
95 having identical chemical composition, will on dissolution exhibit the same chemical
96 behaviour in solution.

97

98 Crystals of a given chemical compound with the same internal structure may exhibit different 99 external shapes or *crystal habits*. In addition, variations in crystal habit may indicate the 100 presence of polymorphism but is not necessarily indicative of polymorphic forms (*12*).

101

Solvates are crystal forms containing stoichiometric or non-stoichiometric quantities of a 102 solvent. When the solvent incorporated into the crystal structure of the compound is water, 103 the molecular adduct formed is referred to as a *hydrate*. Hydrates can be classified as three 104 categories based on different structural aspects: *Class I* represents hydrates where the water 105 molecules exist at isolated sites; Class II hydrates are generally referred to as channel 106 hydrates; and *Class III* hydrates are generally referred to as ion-coordinated site hydrates. In 107 such systems, water molecules form ion-water bonds that are usually much stronger than 108 109 hydrogen bonds (13). Solvation and hydration products are also sometimes referred to as pseudopolymorphs (2, 3, 4). However, the term "pseudopolymorphism" is ambiguous 110 because of its use in different circumstances. It is therefore preferable to use only the terms 111 "solvates" and "hydrates". 112

113

114 Occasionally, a compound of a given hydration/solvation composition may crystallize into 115 more than one crystalline form; an example of such a compound is nitrofurantoin (5). 116 Nitrofurantoin can be crystallized as two monohydrate forms (Forms I and II) and two 117 anhydrous forms (designated polymorphs α and β) (5).

118

119 Crystal forms are said to be *isostructural* (also referred to as *isomorphous*) when they have 120 the same overall crystal packing. Solvates, which have the same overall crystal packing, but 121 differ only in the solvents included in their crystal structures, are termed *isostructural or* 122 *isomorphous solvates*, e.g. hydrate and isopropanolate of hexakis(2,3,6-tri-O-acetyl)- α -123 cyclodextrin (6).

124

125 The term *desolvated solvate* (or *desolvated hydrates*), also referred to as *isomorphous* 126 *desolvates*, has been used to describe a solid form obtained by removing solvent from the 127 solvate crystal structure (or water from a hydrate) without significantly changing the crystal 128 structure (4), as in the desolvated monohydrate of terazosin HCl (7).

129

Amorphous forms of APIs and excipients are of substantial interest because they are usually more soluble (also having a faster kinetic solubility) than their crystalline counterparts but are thermodynamically less stable. Solid-state properties of amorphous forms of the same chemical compound (i.e. thermal behaviour, solubility profile, density, etc.) may differ;

134

135 *Co-crystals* are crystalline materials composed of two or more different molecules, typically 136 an API and co-crystal formers ("coformers") within the same crystal lattice that are 137 associated by nonionic and noncovalent bonds. An example of a co-crystal is the succinic 138 acid co-crystal of fluoxetine HCl (8). Co-crystals are thus more similar to solvates, in that 139 both contain more than one component in the lattice. However, for co-crystals the coformer 140 is non-volatile (i.e. exists as solid material at ambient conditions) (3).

141

Pharmaceutical co-crystals have gained considerable attention as alternative forms in an attempt to enhance the bioavailability, stability and processability of the API in the manufacturing process. Another advantage of co-crystals is that they generate a diverse array of solid state forms for APIs that lack ionisable functional groups, which is a prerequisite for salt formation (*3*). Guidance and reflection papers on the use and classification of pharmaceutical co-crystals have been published (*3*, *9*).

148

149 2. CHARACTERIZATION AND THERMODYNAMIC STABILITY OF SOLID 150 FORMS

151

152 Crystalline and amorphous forms are characterized based on their physicochemical
153 properties. Table 1 lists some examples of the properties that may differ among different
154 forms (9).

Table 1. Examples of physicochemical properties that may differ among different forms

Table 2 summarizes some of the most commonly used techniques to study and/or classify different amorphous or crystalline forms. These techniques are often complementary and it is indispensable to use several of them. Demonstration of a non-equivalent structure by single crystal X-ray diffraction is currently regarded as the definitive evidence of polymorphism. X-ray powder diffraction and/or solid state NMR can also be used, as bulk techniques, to provide unequivocal proof of polymorphism (10).

203

Any technique(s) chosen to confirm the identity of the specific form(s) must be proven to be suitably specific for the identification of the desired form(s). Care must be taken in choosing the appropriate sample preparation technique, as heat generation, mechanical stress or exposure to elevated pressure and other environmental conditions (humidity) may trigger conversion between different forms.

209

225	1	

Using suitable analytical techniques, the thermodynamic stability of the forms should be investigated. The form with the lowest free energy is the most thermodynamically stable at a given temperature and pressure. All other forms of the given system are in a metastable state. At standard temperature and pressure, a metastable form may remain unchanged or may change to a thermodynamically more stable form. In general, the more stable the form the less soluble it is. Conversion to a thermodynamically more stable form, may cause changes in some of the physicochemical properties (see Table 1) of the compound that may result in
changes to other critical properties such as bioavailability, manufacturability (also referred to
as processability), etc.

235

If there are several crystalline forms one form is thermodynamically more stable at a given
temperature and pressure. A given crystalline form may constitute a phase that can reach
equilibrium with other solid phases and with the liquid and gas phases.

239

If each crystalline form is stable within a given temperature range the change from one form to another is reversible and is said to be *enantiotropic*. The change from one phase to another is a univariate equilibrium so that at a given pressure this state is characterized by a transition temperature. However, if only one of the forms is stable over the entire temperature range, the change is irreversible or *monotropic (11)*.

- 245
- 246

3. RELEVANCE OF POLYMORPHISM FOR APIs AND FPPs

247

Polymorphism (and hydrate formation) of APIs and excipients are of interest as they may 248 249 affect bioavailability, toxicity and processability. Also, the thermodynamic stability of the form included in the FPP is considered important as environmental conditions may 250 251 compromise the stability thereof. For formulations where the API is dissolved, attention has to be paid to supersaturation with regards to different forms. A formulation might not be 252 supersaturated regarding a metastable polymorph but supersaturated with regards to the 253 thermodynamically stable polymorph. Control of the form by the manufacturer may be 254 required during the processing of APIs and excipients and during the manufacturing of a 255 dosage form to ensure the correct physicochemical characteristics thereof. The control of a 256 specific form is especially critical in the areas where the bioavailability, stability or 257 processability are directly impacted (4). 258

259

The form of a readily soluble API that is incorporated into a solution, for example, an injection, an oral solution or eye drops, is normally non-critical (exceptions to this statement might be if the concentration of the solution is such that it is close to the limit of solubility of one of the possible polymorphs – as mentioned above - or solvate formation is observed with one of the excipients). Similarly, if an API is processed during the manufacturing process to obtain an amorphous form (e.g. hot melt extrusion, spray-dried dispersion, etc.), the original
form is considered non-critical, as long as the processability is not influenced.

267

The form may be critical when the material is included in a solid dosage form or as a 268 suspension in a liquid dosage form. In such cases, the characteristics of the different 269 polymorphs may affect the bioavailability or dissolution of the material. The polymorphic 270 form of a biopharmaceutics classification system (BCS) class I or III API in a solid oral 271 dosage form is normally non-critical in terms of dissolution rate or bioavailability as by 272 definition it would be readily soluble, but confirmation thereof by the manufacturer, is 273 recommended. The ICH Harmonised Tripartite Guideline on Specifications: Test procedures 274 and acceptance criteria for new drug substances and new drug products: Chemical substances 275 Q6A, provides guidance on when and how polymorphic forms should be controlled and 276 monitored (4). 277

278

The inclusion of potentially harmful solvents in the crystal lattice, which may render APIs or excipients to be toxic or harmful to patients (i.e. solvates), should also be suitably regulated and monitored by the manufacturer.

282

283 4. POLYMORPHISM IN THE INTERNATIONAL PHARMACOPOEIA

284

Where a monograph indicates that a compound shows polymorphism this may be true crystal polymorphism, occurrence of solvates/hydrates or occurrence of the amorphous form.

287

The International Pharmacopoeia controls the polymorphic or crystalline forms (hereafter
referred to as form) of a limited number of substances by restricting it to either:

- 290
- a single form, for example, carbamazepine API (Anhydrous Form III), mebendazole
 API (Form C); or
- by limiting the presence of unwanted forms, for example, chloramphenicol palmitate
 API (should contain at least 90% of polymorph B).
- 295
- 296
- 297

The control of forms specified in *The International Pharmacopoeia* may be achieved by: 298 299 permitting no deviation from the infrared absorption spectrum of the reference 300 301 substance prescribed (or reference spectrum supplied) – when the infrared absorption spectrum has been proven to be specific to the preferred form and able to distinguish 302 the undesired form(s), for example, indomethacin API; 303 restricting the melting point range, when the melting properties of the forms are clearly 304 • distinguishable, for example, phenobarbital API; 305 recommending the use of any other suitable methods such as X-ray powder 306 • diffractometry, for example, carbamazepine tablets; and 307 limiting the incorporated solvent (in the case of solvates/hydrates) with a specific limit 308 test, for example, nevirapine hemihydrate API. 309 310 The specific control to be used will be indicated in the applicable monograph. 311 312 When the infrared identification test is able to detect differences in forms for a specific 313 compound (i.e. polymorphism may be present for this compound), but the control of a 314 315 specific form is not required by the monograph, the user may be instructed to: 316 recrystallize both the test substance and the specified reference substance, in the event 317 • where the infrared spectra are found to be not concordant, for example, fluconazole 318 API; and/or 319 dry the API and/or specified reference substance to ensure that both forms are in the 320 anhydrous or dehydrated state, for example, nevirapine hemihydrate API. 321 322 Whenever the choice of a specific form is critical with regard to bioavailability and/or 323 stability, the method of the manufacturer of the product must be validated to consistently 324 yield the desired polymorph in the final product at release and over its shelf life. The 325 monograph will include a statement under the heading "Manufacturing" to draw attention to 326 the control of a specified form during manufacturing where control is known to be critical, 327

- 328 for example, carbamazepine oral suspension.
- 329
- 330

It is the intention of *The International Pharmacopoeia* to extend the inclusion of explicit statements in monographs, where appropriate, as information on the occurrence of polymorphism becomes available. The Secretariat thus cordially invites the users of *The International Pharmacopoeia* and manufacturers to share any relevant information that could be included in the monographs.
